NEW PHYSICS IN CHARM RADIATIVE DECAYS

Nita Sinha The Institute of Mathematical Sciences Chennai

Why look at Charm Radiative Decays?

Charm is neither heavy, nor light, so neither HQET, nor, chiral perturbation theory can be used.
Direct search for BSM has been unsuccessful so far.
Some anomalies in the Flavour sector.
Rare meson decays, provide a path for new physics searches.

Need to look at all possible avenues not only for finding New Physics, but also for pinning down 'the' model of New Physics.

SHORT DISTANCE VS LONG DISTANCE

While in case of B mesons, short-distance effects dominate, charm quark systems are dominated by large long-distance QCD contributions.

Within the SM, the short distance in rare charm decays Suffers from almost complete GIM suppression, as box or penguin diagrams get contributions from down type-almost massless quarks from the weak scale perspective.

RENCONTRES DU VIETNAM FLAVOUR PHYSICS ICISE 2017

8/16/2017

The long distance effects can screen the presence of new physics particles that may appear in the loop of the short distance penguin contributions.

NP short distance enhancement should be larger than the long distance contributions, to be distinguishable

Alternately, look for special observables

Measure the difference in the rates of the exclusive modes, $D^0 \rightarrow \rho \gamma$ and $D^0 \rightarrow \omega \gamma$ in which the long distance effects are expected to cancel, would indicate short distance new physics if the data reveals a difference of rates which is more than 30%. FAJFER et. al, PHYS. LETT. B487, 81 (2000)

We will demonstrate that measurement of the photon polarization can be used to signal new physics.

Explore effects of presence of a heavy-vector like down type isosinglet quark with additional L-R symmetry. No Z-mediated FCNC in the up type quark sector. RENCONTRES DUVIETNAM FLAVOUR PHYSICS ICISE 2017 8/16/2017 5

Enhancement of rates:

with QCD Corrections

Within SM, there is an enhancement of the radiative decay rates in the presence of QCD corrections. Enhancement by a factor of 2 in $b \rightarrow s \gamma$. A more dramatic enhancement expected in the case of charm radiative decays. Hence need to evaluate the corresponding Wilson coefficients within the RG improved perturbation theory.

with NP

Need to enhance the rate above that from long distance Effects OR need signals that can be observed even in the presence of the long distance effects.

RENCONTRES DU VIETNAM FLAVOUR PHYSICS ICISE 2017

Short Distance QCD corrections in the SM

It was shown (Greub, Hurth, Mísíak, Wyler), that there is an enhancement from $O(10^{-17})$ to $O(10^{-8})$ of the **BR** with NLO QCD corrections. GREUB et. al., PHYS.LETT. B 382(1996) 415.

vector-like down type isosinglet quark

- Possibility of short-distance enhancement in heavy vector like fermion models discussed previously BABU et. al., PHYS. LETT. B205, 540 (1988).
 - No new operators are introduced for the $c \rightarrow u\gamma$ transition
- Above the b scale, one needs to integrate Out b' also.
 - The operators $\mathcal{O}_7, \mathcal{O}_8$ contribute above the b scale, due to presence of b' quark.
 - A chí-squared fit to many flavor observables was performed to obtain the preferred central values of all the elements of the measurable 3X4 quark mixing matrix. ALOK et. al., NUCL. PHYS. B 906, 321 (2016)

RENCONTRES DU VIETNAM FLAVOUR PHYSICS ICISE 2017

Branching Ratios in SM and in a model with Vector like quark

QCD corrections	$\mid A \mid$			$BR(c \rightarrow u\gamma)$		
	SM	VLQ	VLQ	SM	VLQ	VLQ
		$m_{b'} = 800 \; {\rm GeV}$	$m_{b'} = 1200 \; {\rm GeV}$		$m_{b'} = 800 \; { m GeV}$	$m_{b'} = 1200 \text{ GeV}$
Bare	$2.73 imes 10^{-7}$	2.49×10^{-5}	$2.35 imes 10^{-5}$	2.04×10^{-17}	1.70×10^{-13}	1.51×10^{-13}
LO	$5.89 imes 10^{-6}$	4.32×10^{-5}	4.25×10^{-5}	9.48×10^{-15}	$5.11 imes 10^{-13}$	4.94×10^{-13}
NLO	2.61×10^{-3}	4.46×10^{-2}	$4.37 imes 10^{-2}$	1.86×10^{-9}	$5.46 imes 10^{-7}$	$5.23 imes10^{-7}$

At the LO, contributions from the intermediate s and d quarks differ only in the CKM factors, their sum, using unitarity is $-V_{cb}^*V_{ub}$ leading to a large suppression in the amplitude. At NLO, the functional dependence of the amplitudes on s and d quark masses becomes substantial, the amplitude is $\propto V_{cs}^*V_{us}$ and is enhanced.

Photon Polarization as a probe of New Physics Within SM, in the penguin diagram for $c \rightarrow u\gamma$, only LH components of the external fermions couple to the W.

A helicity flip on the c quark leg $\propto m_c$, contributes to amp. for emission of left polarized photons, while that on the u quark leg, $\propto m_u$, results in right polarized photons.

In the LRSM, since the physical W_1 couples to both left and right handed quarks, a helicity flip is also possible on the internal (d,s,b) quark lines, $\propto m_b \zeta$.

With the additional vector like quark, $\propto m_b, \zeta$

RENCONTRES DUVIETNAM FLAVOUR PHYSICS ICISE 2017

Photon polarization for the process, $c \rightarrow u\gamma$

We define the photon polarization for the $c
ightarrow u\gamma$ process as,

$$\lambda_{\gamma} = \frac{|c_R|^2 - |c_L|^2}{|c_R|^2 + |c_L|^2}$$

where c_R, c_L denote the amplitudes for the right and left polarized photons in the process.

For SM, since SD contributions to c_R are negligible, with only SD contributions, $\lambda_{\gamma} = -1$.

However, the exclusive decay modes corresponding to $c \rightarrow u\gamma$ are dominated by LD contributions. To account for these, we add all the pole type and VMD amplitudes of all the exclusive charmed meson processes. Due to the uncertainty in the sign of the VMD, the LD amplitude lies in the range $(2.08 \times 10^{-9} - 8.78 \times 10^{-7}) 1/GeV$

Left-Right Symmetric Model The minimal left right symmetric model is based on the gauge group $SU(3)_c \times SU(2)_L \times SU(2)_R \times U(1)_Y$

The electric charge $Q = I_{3L} + I_{3R} + \frac{B-L}{2}$.

To ensure perturbative interactions between righthanded gauge boson and fermions, $\zeta_g = g_R/g_L$, (where g_R and g_L are the right and left handed couplings) Should not be too large. Direct search impose the bound $\zeta_g M_{W_2} > 2.5 TeV$.

Also, v_R should be in the TeV range. These constraints imply that $0 < \zeta_g < 2$.

RENCONTRES DU VIETNAM FLAVOUR PHYSICS ICISE 2017

Polarization Values

SM case: The LD amplitudes do not have any preferred polarization, they contribute equally to both c_R and c_L . This results in an almost vanishing value of polarization, $\lambda_{\gamma} \sim \mathcal{O}(10^{-8} - 10^{-5})$.

VLQ Without LR symmetry, isosinglet VLQ can only couple to W_L , and hence its addition will only enhance the left Polarized amplitude. For this case, in presence of LD contribution, λ_γ lies in the range $(-6.1 \times 10^{-6} to - 2.6 \times 10^{-3})$

8/16/2017

The Interesting Scenario

The photon polarization can be expressed as a function of $\zeta, \zeta_g, \phi_{12}$ for the case of LRSM and of $\zeta, \zeta_g, \phi_{12}, \phi_{14}, \phi_{24}, \phi_{34}$ for LRSM+VLQ

These parameters are varied within their allowed ranges and one looks for the maximum deviation of the polarization from its SM value.

LR.SM, without and with LD

For very small values of ζ , ζ_g LRSM approaches the SM, hence in absence of long distance contribution, the polarization is left handed ($\lambda_{\gamma} = -1$). However, as the parameters, ζ , ζ_g increase, the polarization changes from -1 to +1

Polarization

Recently an observation of photon polarization in the $b \rightarrow s\gamma$ transition reported by LHCb.

Photon polarization is obtained by the angular distribution of the photon direction with respect to the plane defined by the momenta of the three final state hadrons in their center of mass frame.

A similar technique could be used to measure the photon polarization for the case of $D \rightarrow \omega \gamma$, since the decay of ω into three pions will permit the measurement of an up-down asymmetry between the number of events with photons on either side of the plane.

RENCONTRES DUVIETNAM FLAVOUR PHYSICS ICISE 2017 8/1

On the Experimental side.....

Branching Ratios

Belle

 $BR(D^{0} \to \rho^{0} \gamma) = (1.77 \pm 0.3 \pm 0.07) \times 10^{-5},$ $BR(D^{0} \to \phi \gamma) = (2.76 \pm 0.19 \pm 0.10) \times 10^{-5},$ $BR(D^{0} \to \overline{K}^{*0} \gamma) = (4.66 \pm 0.21 \pm 0.21) \times 10^{-4}.$

Depending on the LD amplitude, NP SD contribution may/may not be allowed.

For $\rho\gamma$, $K^*\gamma$, Photon polarization could be obtained from photon conversion to e^+e^- .

8/16/2017

Conclusions

Charmed decay modes including radiative ones are expected to be plagued by long distance contributions.

For certain values of the parameter space of the model with LRSM and a down type isosinglet vector-like quark, SD BRs could be enhanced by even $\mathcal{O}(10^{10})$ wrt SM SD BR. They could hence be above the long distance contribution.

Such an enhancement could signal the presence of NP. However, the uncertainty in the size of the long distance contributions may not allow this to be easily feasible. However, the photon polarization continues to be different from the SM value, over the entire range of the estimated long distance contributions and hence can in principle be a robust signature of the presence of NP. 20

Long Distance Contributions

These being non-perturbative are hard to estimate. Separated into two classes.

First one corresponds to the annihilation or exchange diagrams $c\overline{q_1} \rightarrow q_2 \overline{q_3}$ with a photon attached to any of the four quark lines. At hadronic level these diagrams manifest as long distance pole diagrams.

The second corresponds to the process $c \rightarrow q_1 \overline{q_2} q$, followed by $\overline{q_2}q \rightarrow \gamma$. At hadronic level this is the vector dominance mechanism (VMD).

Pole Contributions

Vector Meson Dominance

 $D \to V_1 V_2, \, V_2 \to \gamma$

using the factorization assumption, the squared VMD amplitude is:

$$\left|\mathcal{A}_{VMD}\right|^{2} = \frac{G_{F}^{2} \left|V_{cq}^{*} V_{uq'}\right|^{2}}{2m_{D}^{2} \mathbf{k}^{2}} a_{i}^{2} (m_{c}^{2}) f_{X}^{2} I \times \left[\left(m_{D} + m_{Y}\right)^{2} A_{1}^{2} (q_{0}^{2}) + \frac{4\mathbf{k}^{2} m_{D}^{2} V^{2} (q_{0}^{2})}{(m_{D} + m_{Y})^{2}}\right] \times \frac{4\pi\alpha}{\overline{f}_{V_{2}}^{2}}$$

Correspond to Color favoured/ suppressed operators X, is the final meson which couples to vacuum Y, appears from the $D \rightarrow Y$ transition

 $\langle Y(p_Y)|J^{\mu}|D(P)\rangle = \frac{2V(q^2)}{m_D + m_Y} \epsilon^{\mu\nu\rho\sigma} \epsilon^*_{\nu} P_{\rho} p_{Y_{\sigma}} + 2m_Y i A_0(q^2) \frac{(\epsilon^* \cdot q)}{q^2} q^{\mu}$ $+ i \left[(m_D + m_Y) A_1(q^2) \epsilon^{*\mu} - \frac{(\epsilon^* \cdot q) A_2(q^2)}{m_D + m_Y} (P + p_Y)^{\mu} - 2m_Y A_3(q^2) \frac{(\epsilon^* \cdot q)}{q^2} q^{\mu} \right]$

To calculate the form factors, we use the form,

$$A_1(q_0^2) = \frac{A_1(0)}{1 - b'x} , \ V(q_0^2) = \frac{V(0)}{(1 - x)(1 - ax)}$$

Fajfer, Kamenik PRD **72,** 034029 (2005)

The decay constants are determined in terms of $V \rightarrow e^+e^-$ data.
